The car is able to drive at least 4.32 miles without incident...

The car drives according to the speed limit.

Max Acceleration and Jerk are not Exceeded.

Cars do not have collisions.

The car is able to change lanes

To solve these issues the following code really helped slow the car down whenever it was too close to another car.

There were more implementations about these in the preceding lines. Code is commented with explanations.

```
if the car is too close to another car make sure the speed is modified
                                       if (tooClose)
182 -
                                           ref_vel -= 0.224;
if (isLeft != true && isRight != true && lane == 1)
                                               if (speedOfLeftCar > speedOfRightCar)
188 *
                                                    lane -= 1;
                                               else if (speedOfLeftCar < speedOfRightCar)
                                                    lane += 1;
                                           else if (isLeft != true && lane > 0)
                                                lane -= 1;
                                           else if (isRight != true && lane < 2)
200
                                               lane += 1;
                                       // makes sure it it doesnt go over 49.5 mph
                                       else if (ref_vel < 49.5)
                                           ref_vel += 0.224;
```

The car stays in its lane, except for the time between changing lanes.

```
// for collision avoidance
// for collision avoidance
// for collision avoidance
// bool tooClose = false;

// booleans to check in left and right lane are safe
// bool isLeft = false;
// bool isRight = false;

// variables to check for cars similar to the one provided in the video
// variables to check for cars similar to the one provided in the video
// variables to check_right_lane_car, check_left_lane_car;

// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables to determine the speed of the cars in the left and right lanes
// variables the cars in the
```

The following variables were used to make sure the left lane is clear, the right lane is clear, and the speed of the car is checked with the following line located on line 138.

double checkSpeed = sqrt(vx * vx + vy * vy);

The code is commented with explanation in more detail.
